Is Four Better than Two? The Influence of Bilingual and Multilingual Metrics in an Implicit Bilingual Statistical Learning Task

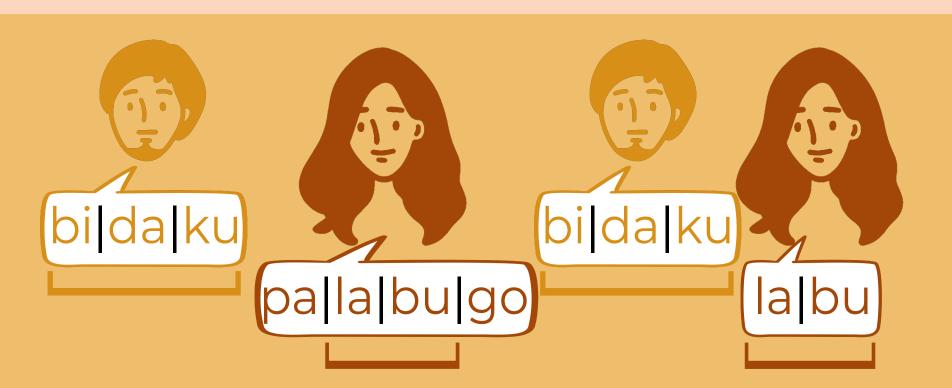

ary Advances in Statistical Learning conference 07/06/2024

Anna Marie Liebelt & Davide Crepaldi

Introduction

Bilingual statistical learning

- ogoal: understand structure of world
- o dual-language learning stream need to track regularities in two languages simultaneously
- o **explicit** cue to language membership: distinct speakers
- o bilinguals can track more complex patterns with fewer explicit cues¹

Bilingual statistical learning task: a constant flow of speech is played, in two distinct voices (red for female, yellow for male) for each language. Each language is composed of individual chunks (morphemes, represented by vertical lines), with some morphemes always appearing together (represented by brackets),

Which multilingual metrics help learning in an implicit bilingual statistical learning task?

Methods

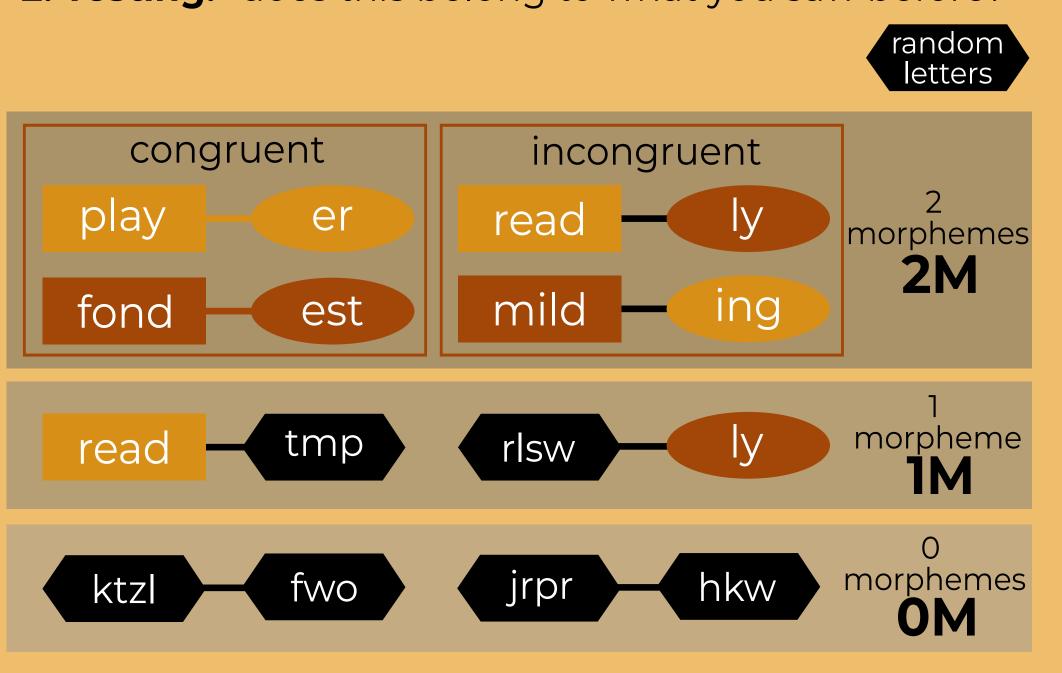

1. Training: "pay attention to the words on the screen"

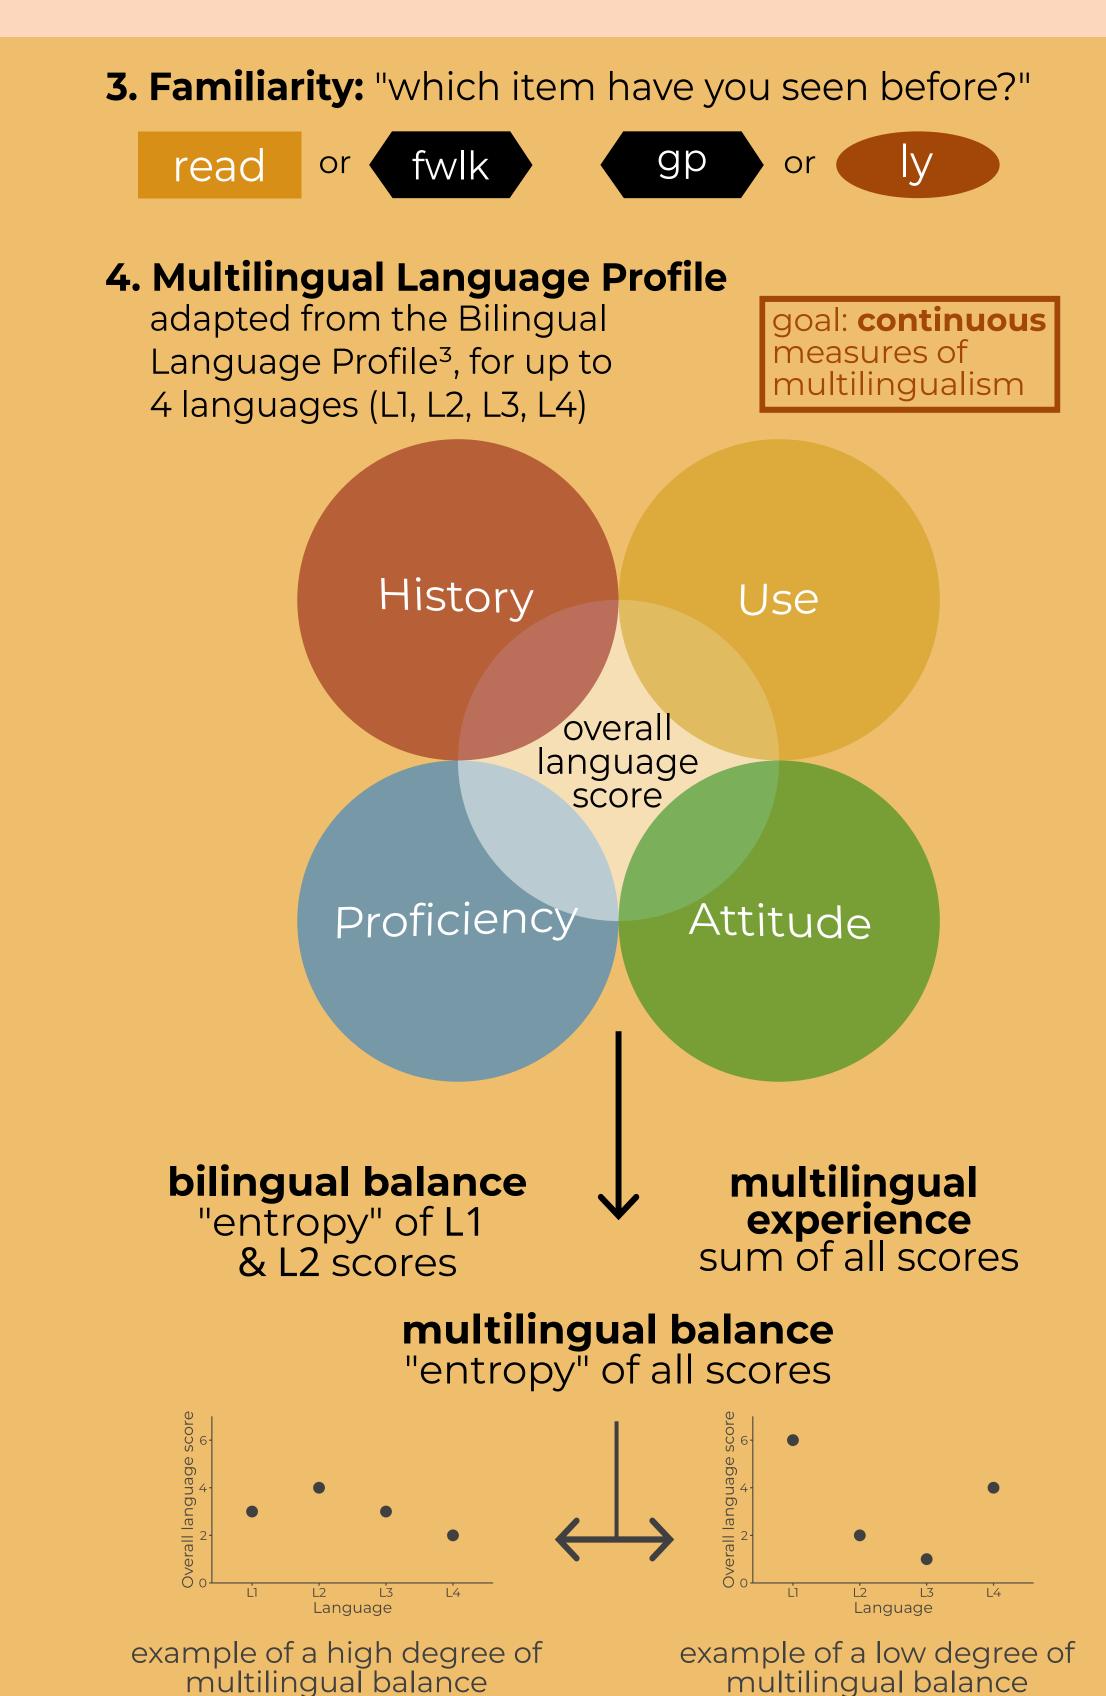

All words presented in BACS-1 font²: KYTCPTR

Participants need to I. Segment words into parts 2. Track co-occurence of parts

2. Testing: "does this belong to what you saw before?"

Results

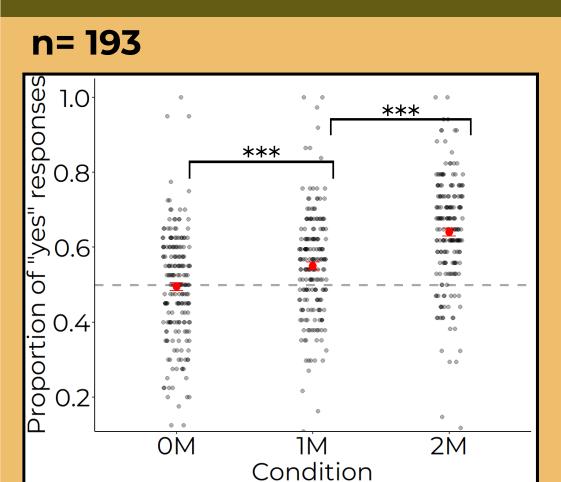

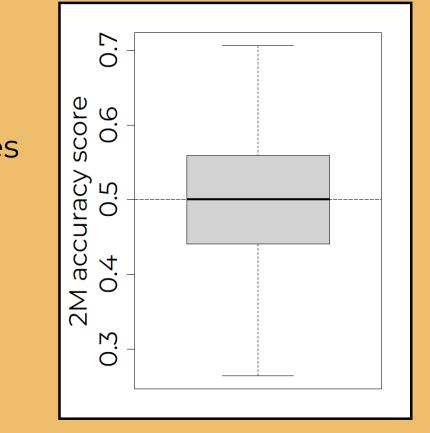

Figure 1: Proportion of "yes" responses in the no morphemes (OM), one morpheme (1M), and two morphemes (2M) testing conditions.

Group means are shown by a red circle with error bars.

Chance level (0.5) is shown as a dotted line.

Figure 2: Boxplot of the accuracy scores in the 2M condition.

Chance level (0.5) shown as a dotted

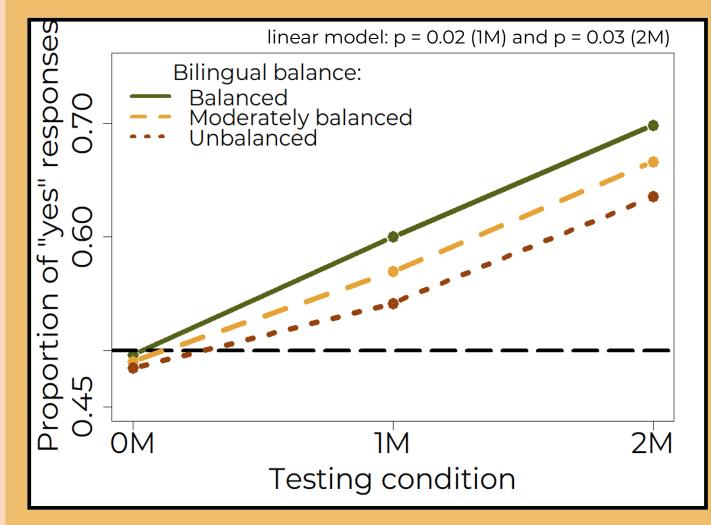

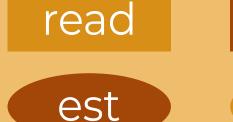

Figure 3: model fit for the interaction of the amount of "yes" responses in each condition and different amounts of imbalance of participants' scores for their first two languages.

Chance level (0.5) shown as a dotted line.

EXPERIMENT 2

IDENTICAL METHODS TO EXPERIMENT 1, WITH THE ADDITION OF:

0.5. Pre-training: "spell these word parts"

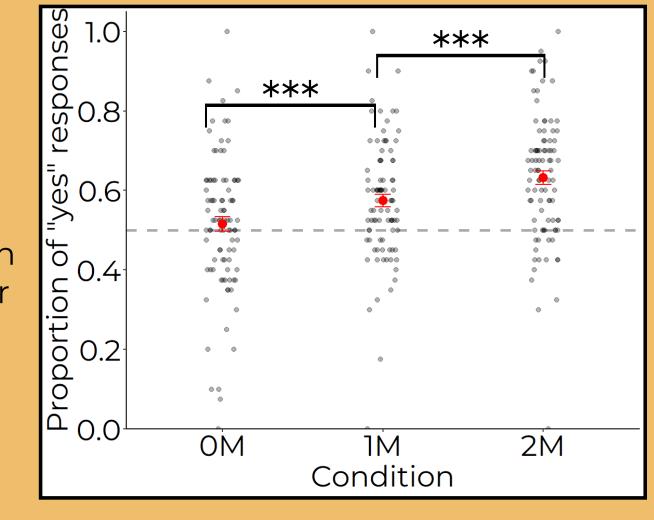

Participants need to only track <u>co-occurence</u> of parts

n= 91

Figure 4: Proportion of "yes" responses in the OM, 1M, and 2M testing conditions.

Group means are shown by a red circle with error

Chance level (0.5) is shown as a dotted line.

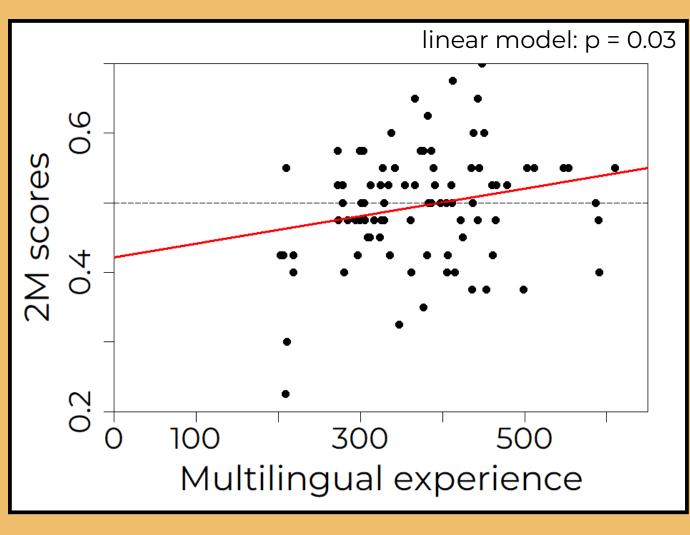

Figure 5: model fit for the interaction of scores in the 2M condition and the amount of multilingual experience.

Chance level (0.5) shown as a dotted

Discussion

Greater number of familiar morphemes higher chance of responding "yes"

O expansion of Lelonkiewicz et al. (2020)⁴

Group 2M performance at chance level

O task too difficult OR no multilingual metrics with significant effect

More balanced bilinguals say "yes" more when there are more familiar morphemes

o no significant interaction with multilingual balance - strictly **bi**lingual phenomenon?

Greater number of familiar morphemes higher chance of responding "yes"

O same as in experiment 1

Group 2M performance still at chance level

O task still too difficult to see group-level effect

More experienced multilinguals have higher 2M accuracy

o more **multi**lingual experience - more experience tracking mutliple statistical systems - better able to track co-occurences in a novel dual-language environment

Does balance or experience matter more? Does it depend on task difficulty?

"yes" responses collected in every condition

→ 2M accuracy scores
